Matter

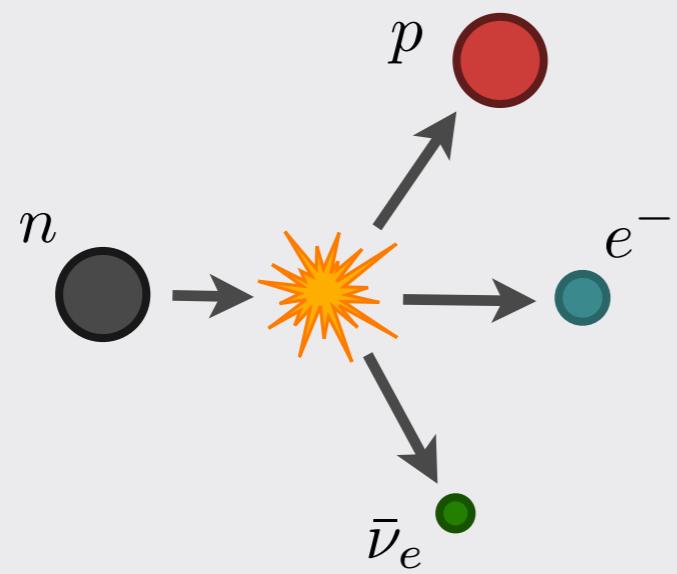

Electromagnetism

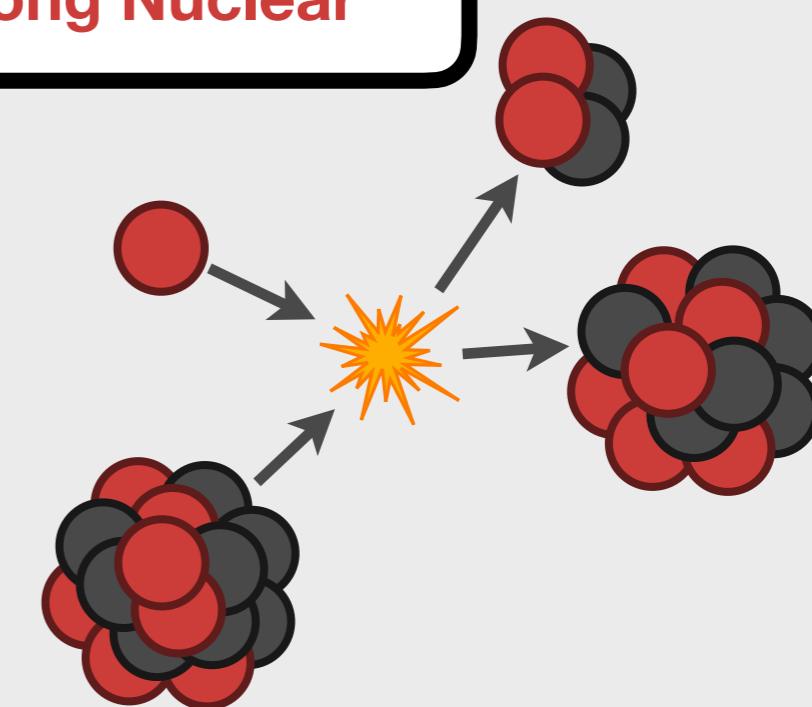

Gravity

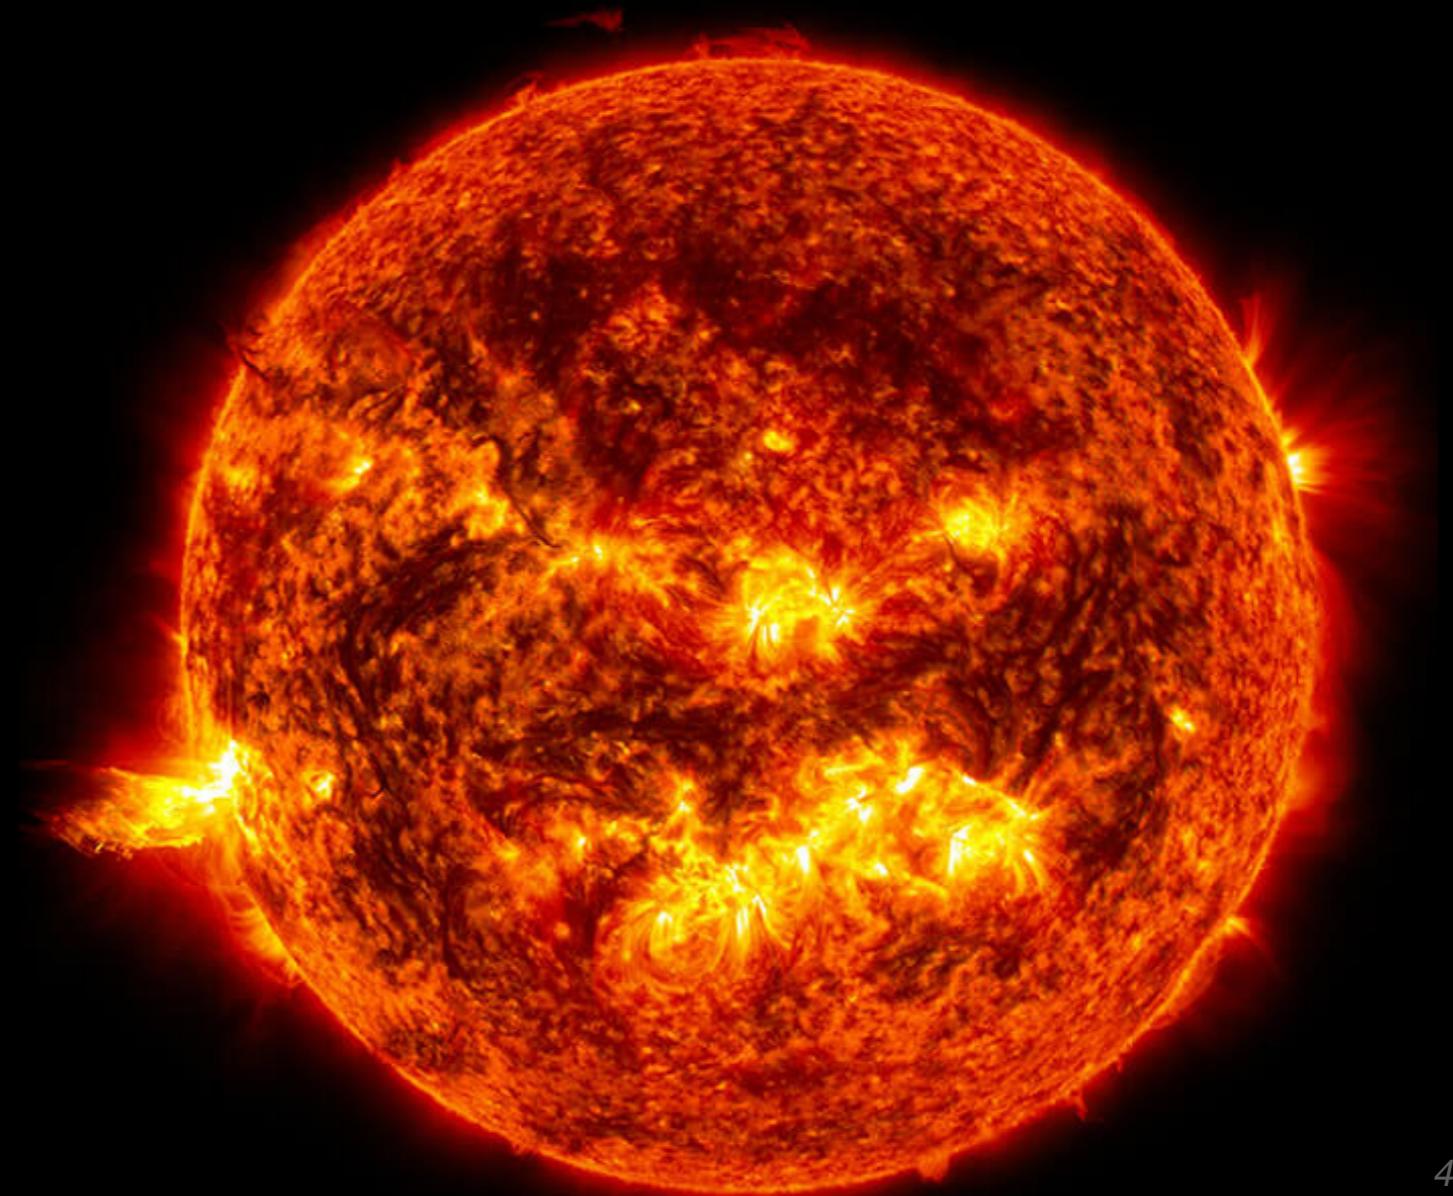

Weak Nuclear

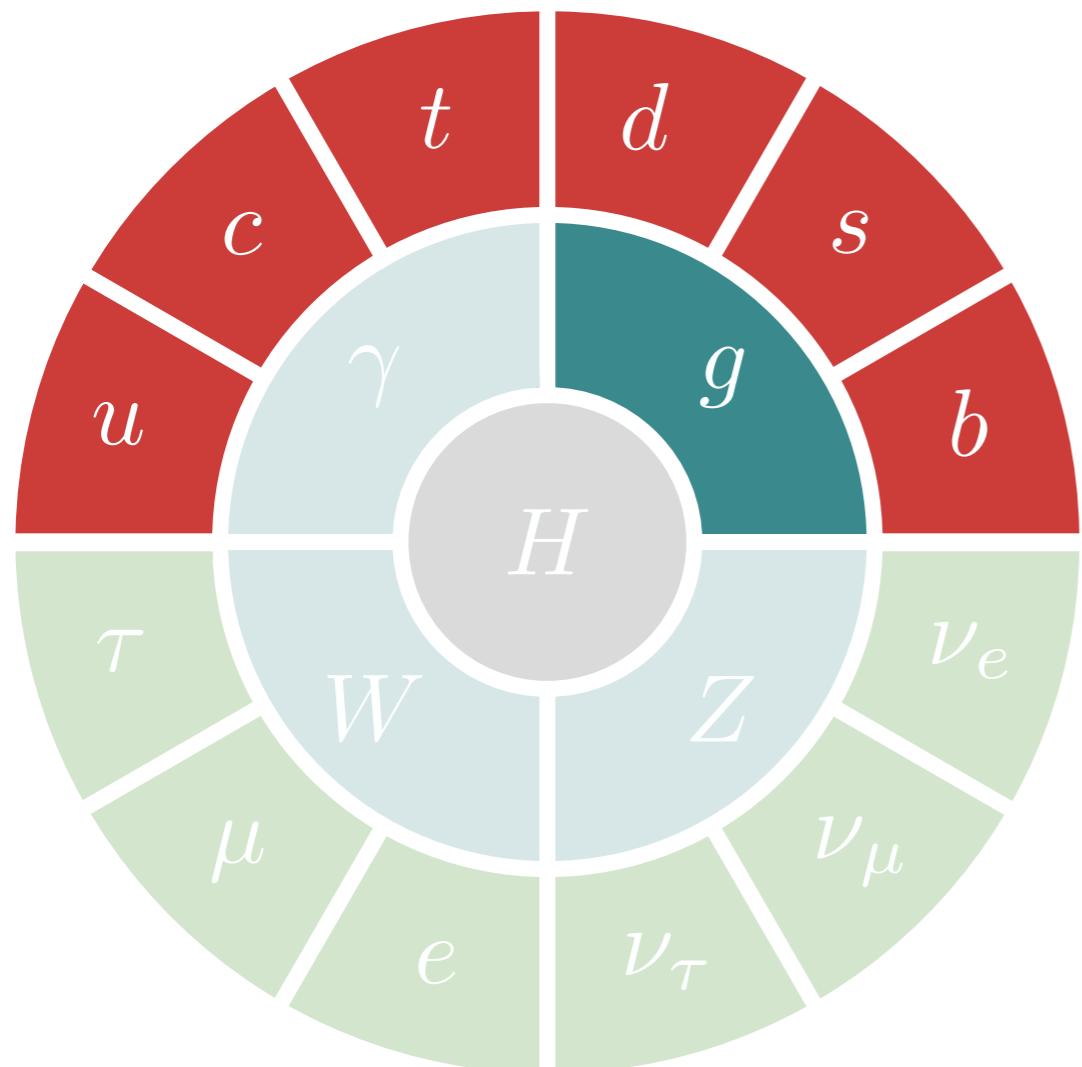

Strong Nuclear

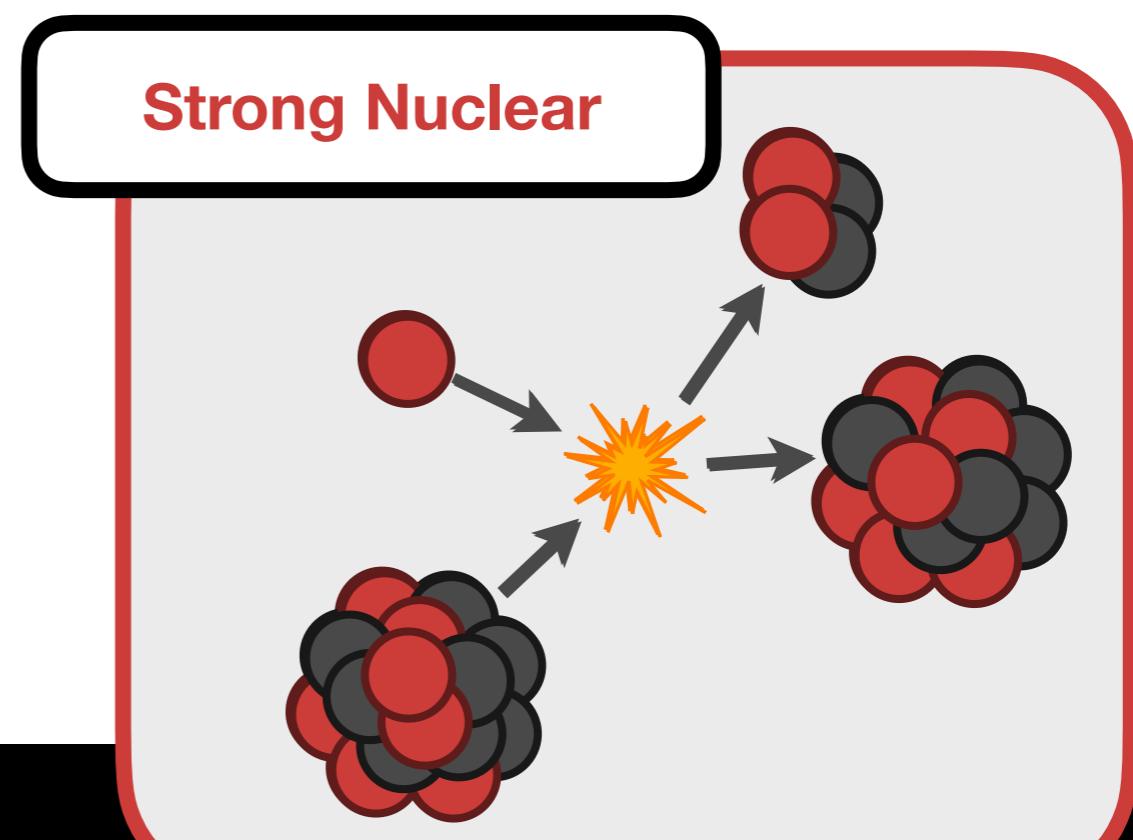

The Standard Model of Particle Physics

Nature can be described by a remarkably *simple** theory

Matter		Force Carriers	
Quarks	Gauge Bosons	Leptons	Higgs Boson

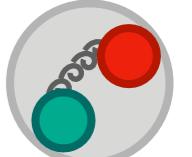

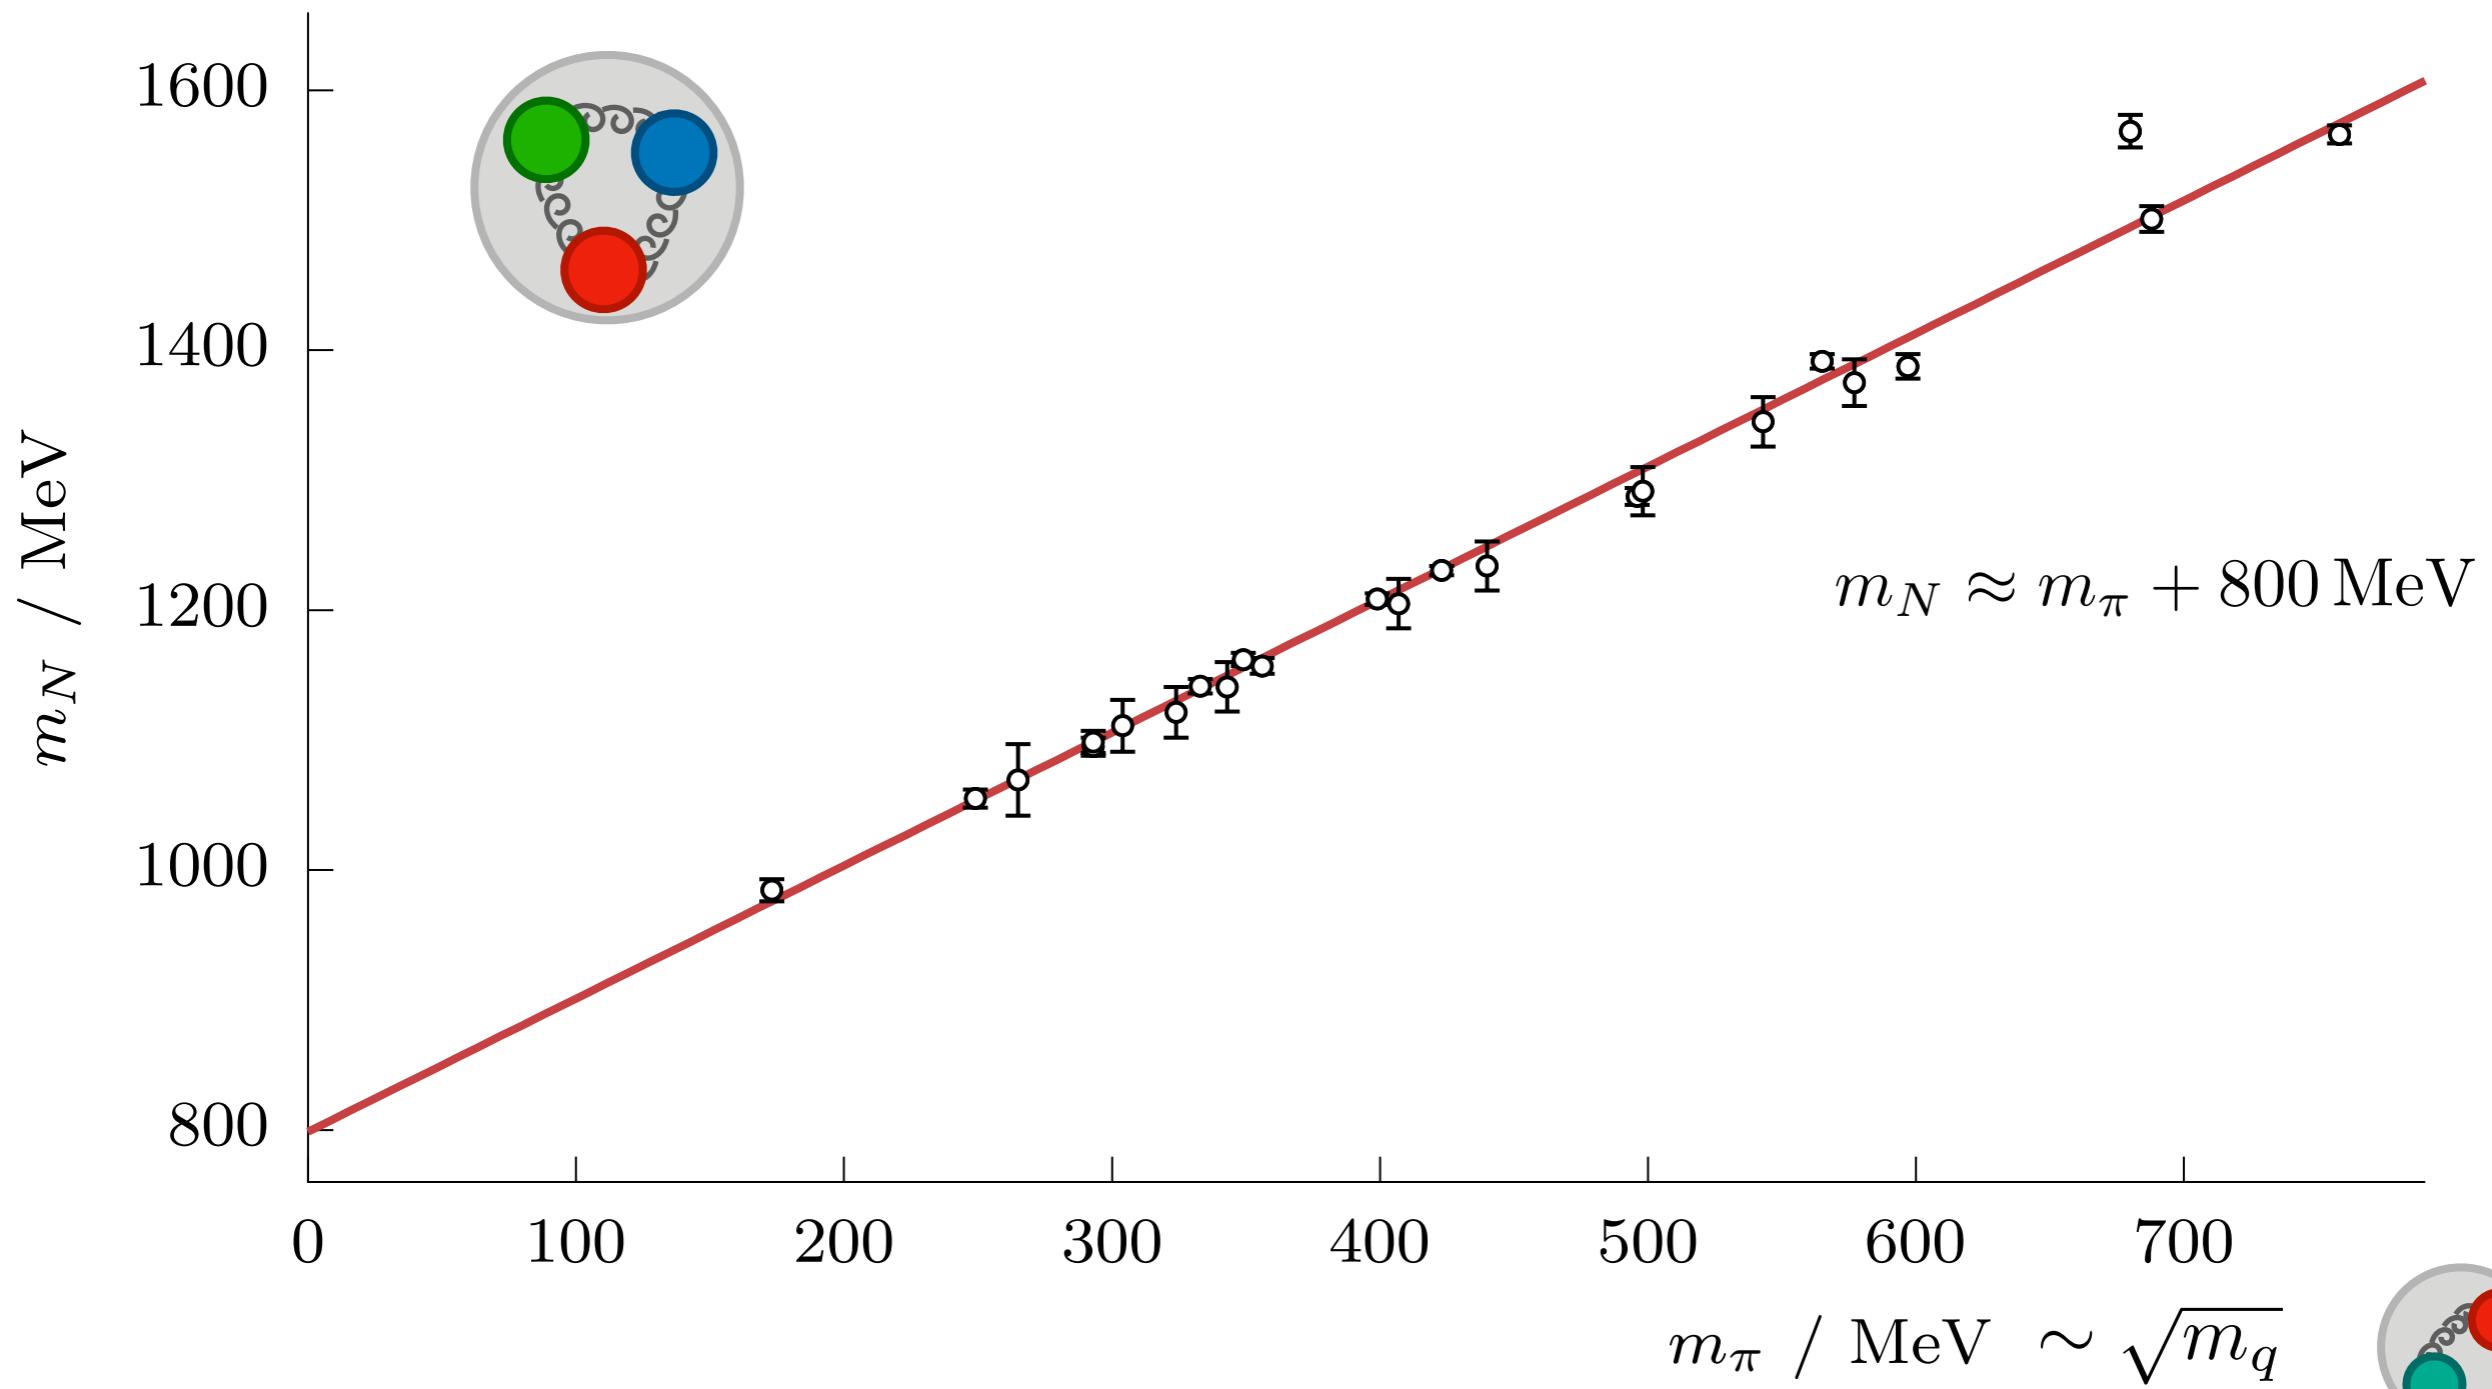

Quantum ChromoDynamics (QCD)

* simple = An a

invariant under the gauge group $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$
which spontaneously breaks via a scalar field to $SU(3)_C \otimes U(1)_Q$

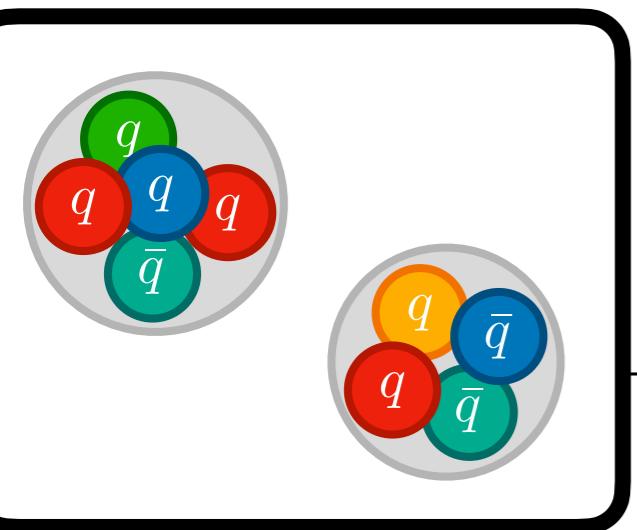

Nuclear Forces

Most of our mass comes from nuclear forces!

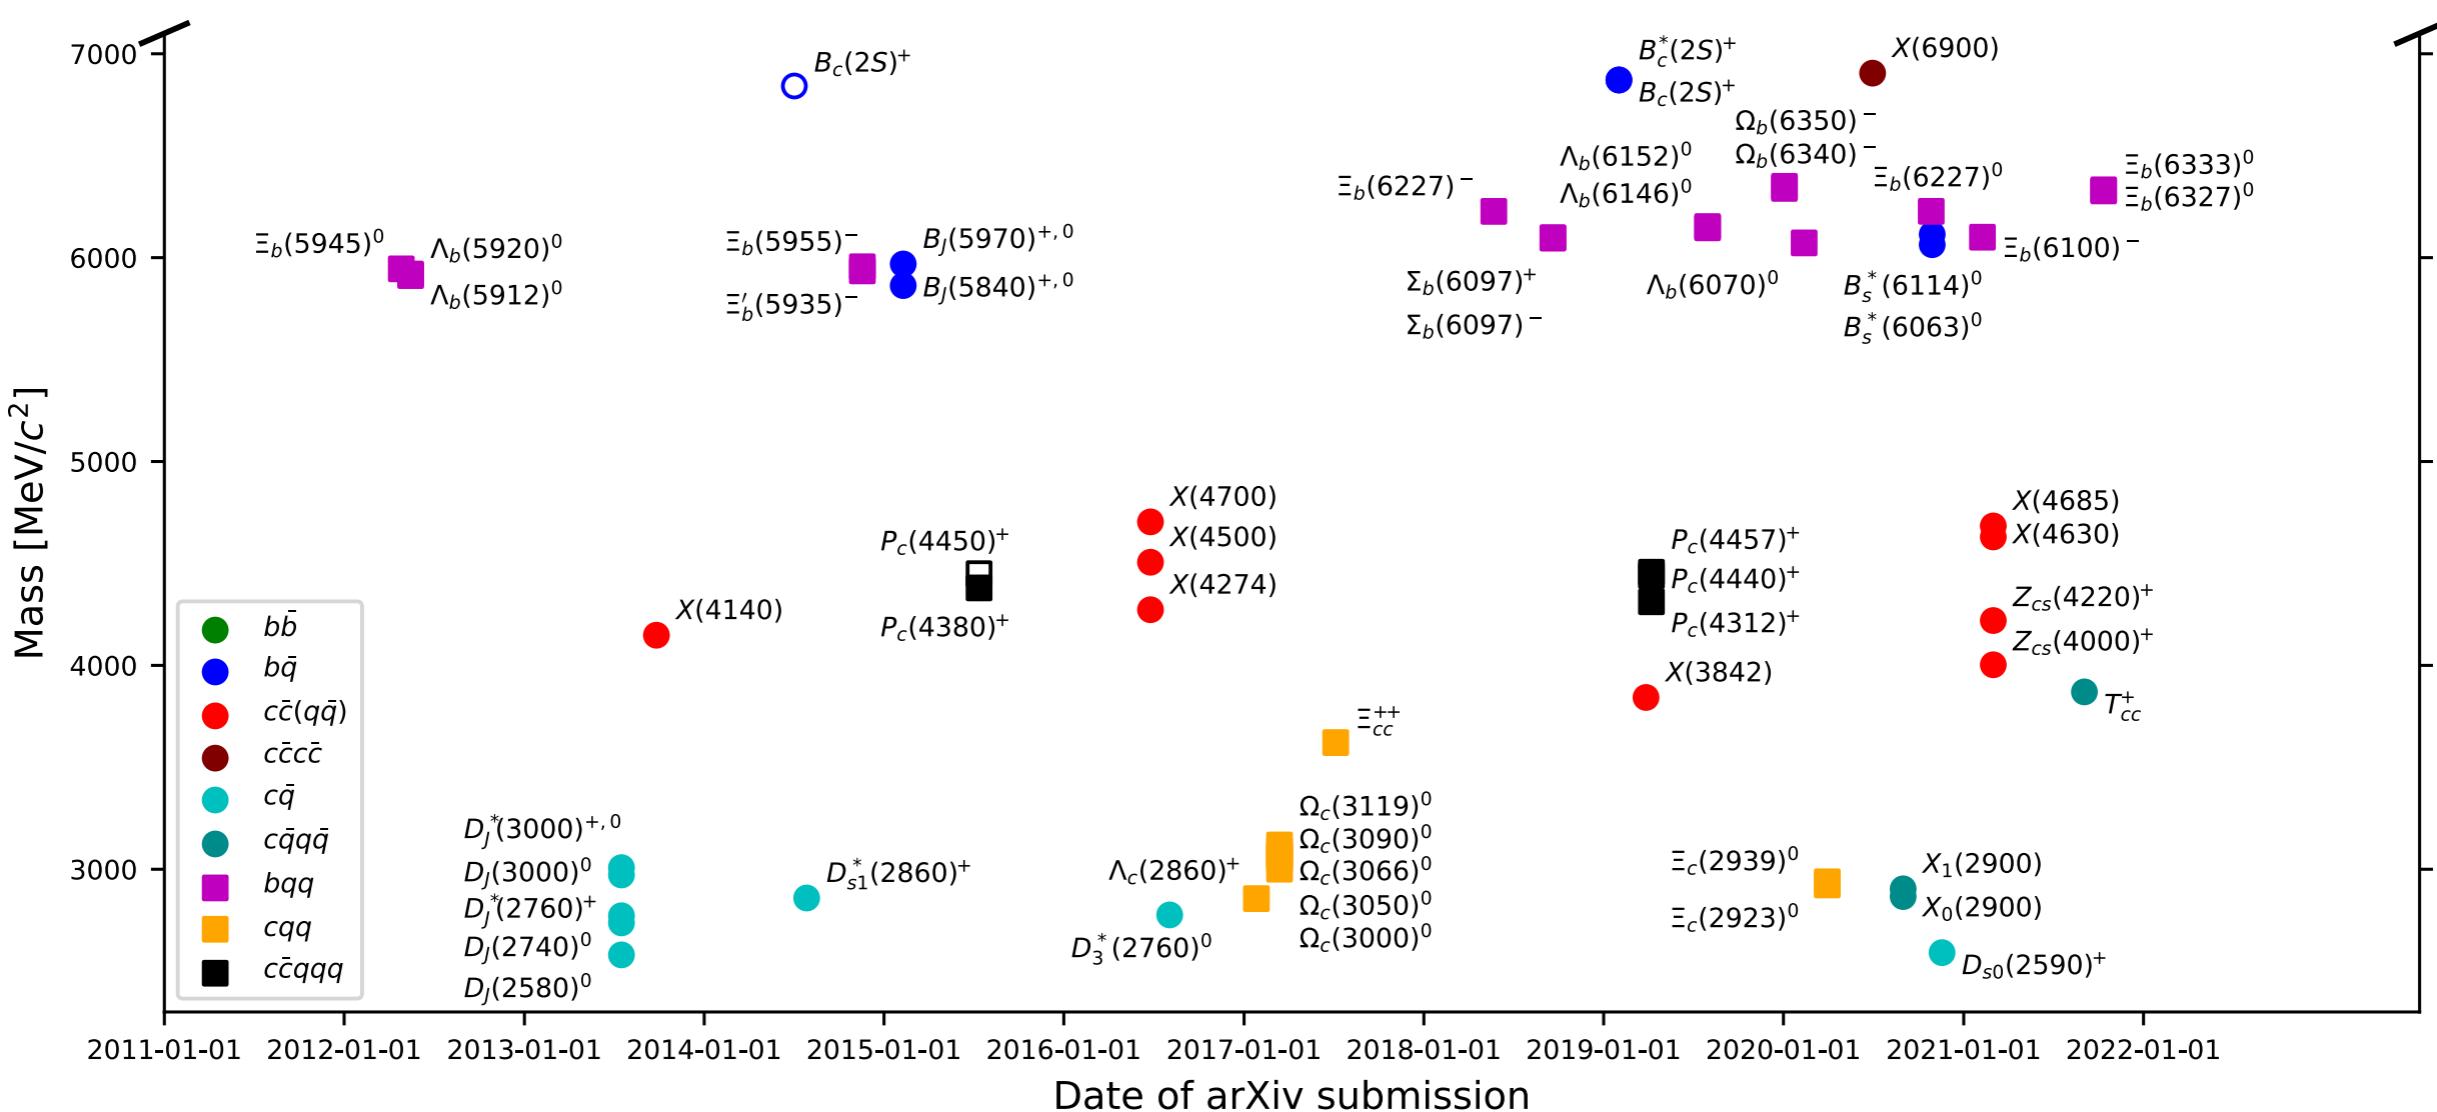

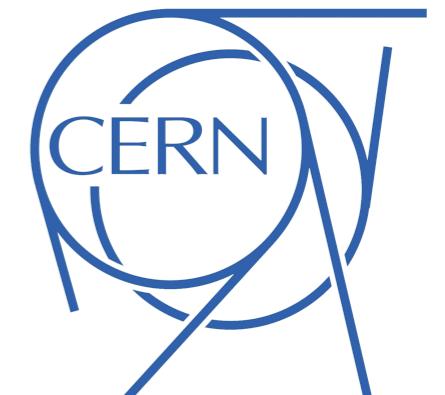

New discoveries in Nuclear Physics

Zoo of *exotic* quark configurations discovered

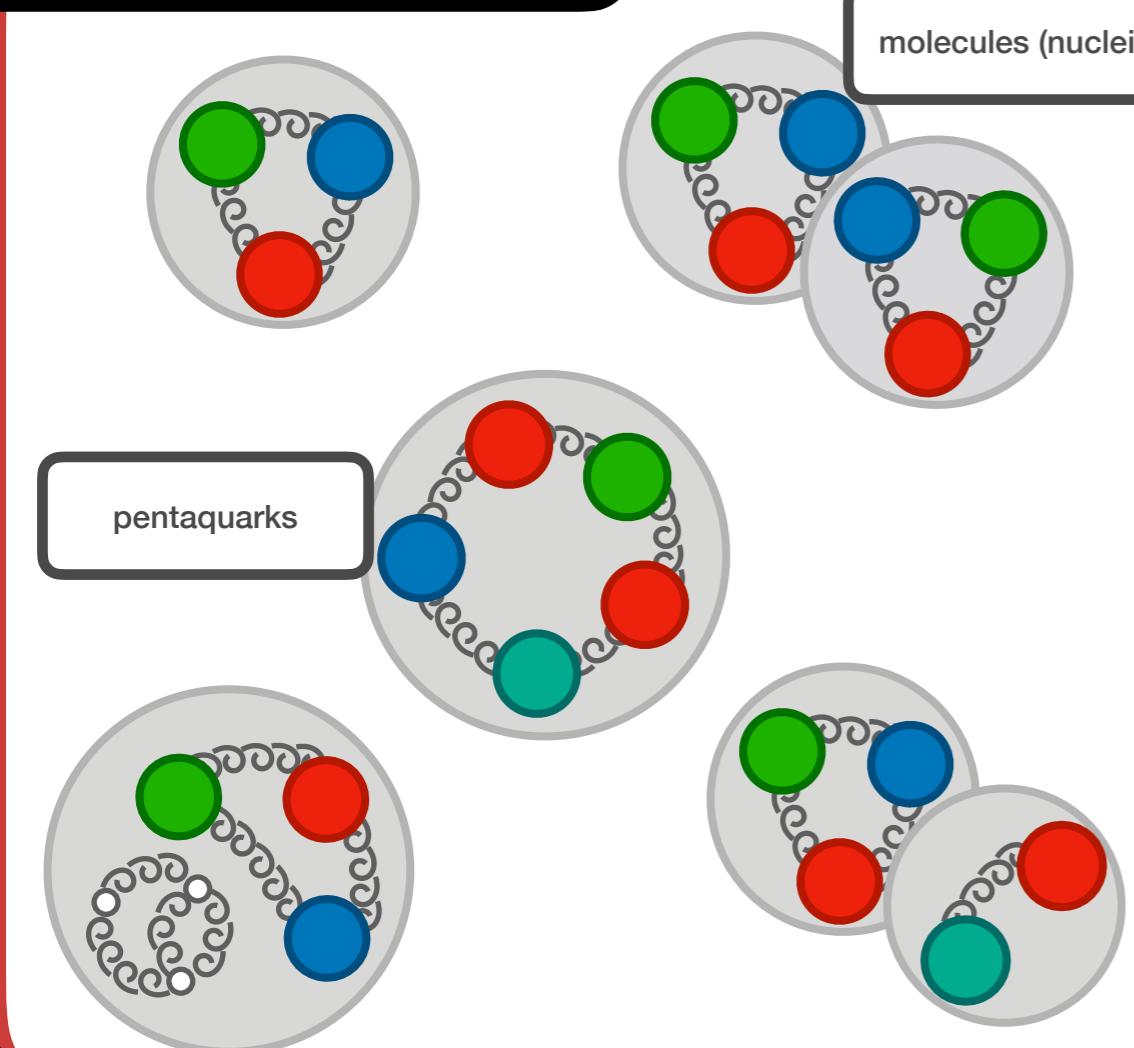

62 new hadrons at the LHC

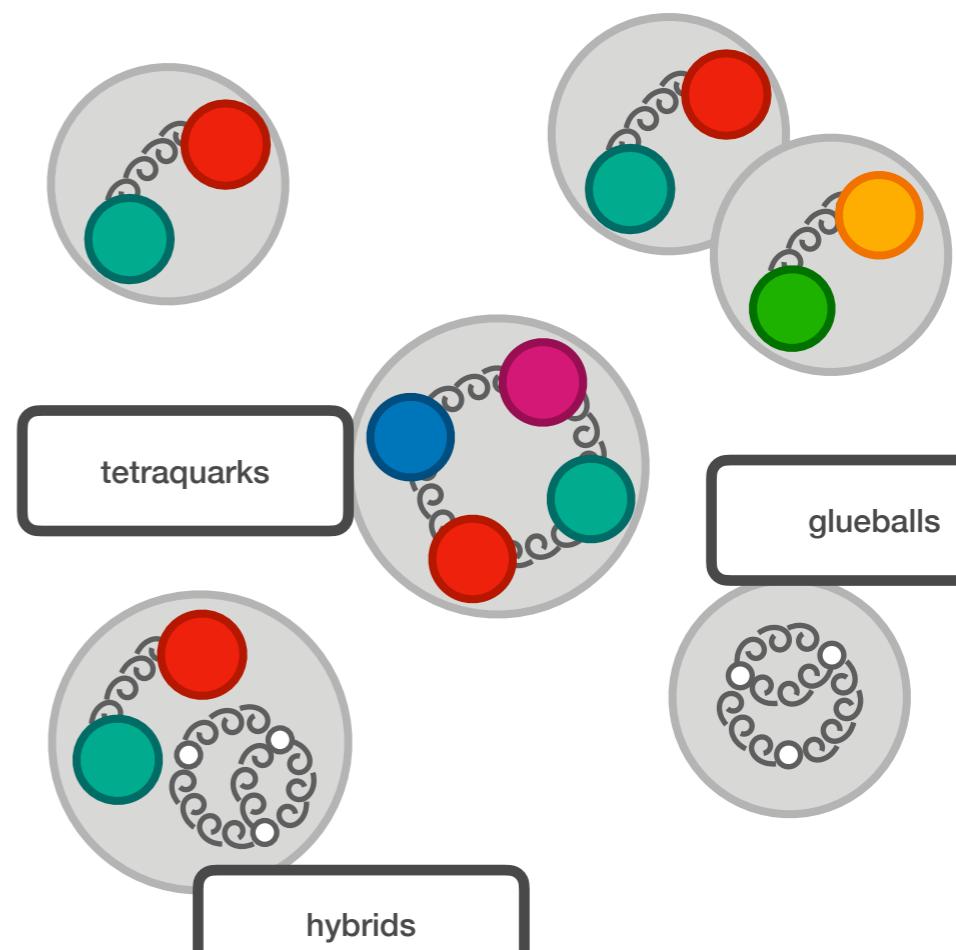

Many types of nuclear particles

A zoo of particles — How to understand?

Baryons (fermions)

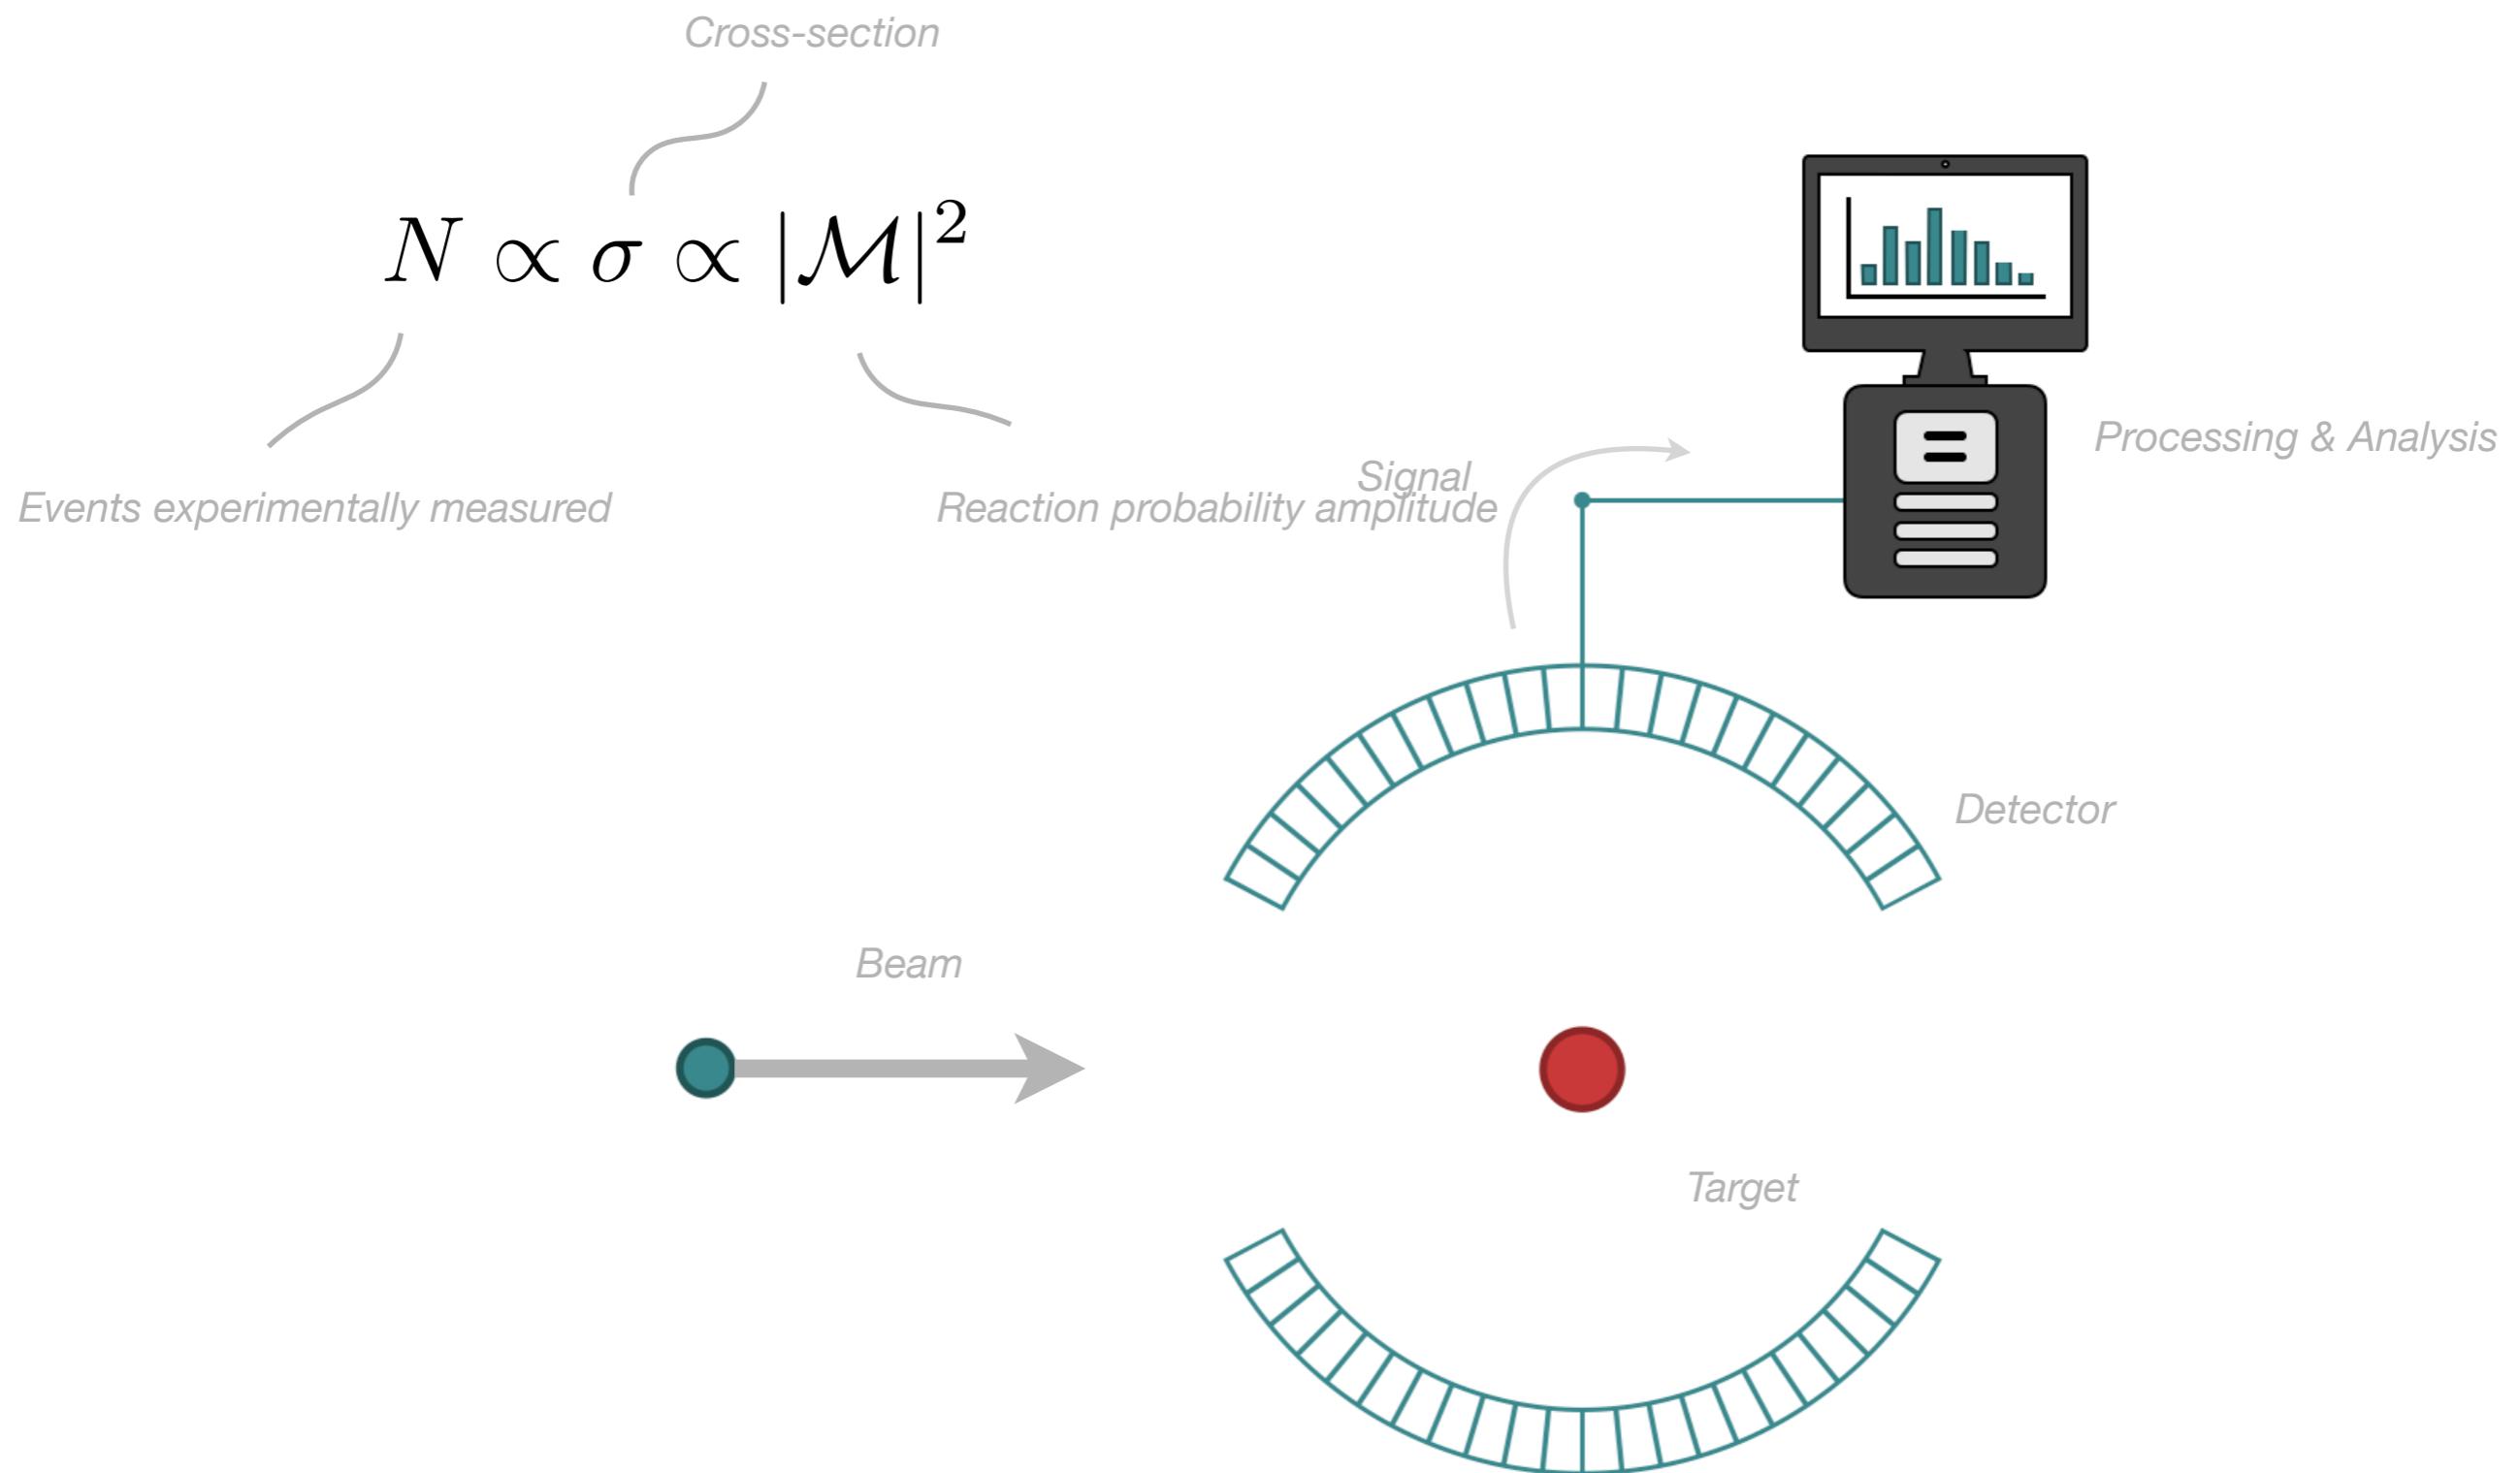

Mesons (bosons)

Observing Hadrons

We observe strongly interacting hadrons through reactions in accelerators/colliders

Observing Hadrons

We observe strongly interacting hadrons through reactions in accelerators/colliders

- If the interaction is sufficiently attractive, particles can form a **resonance**

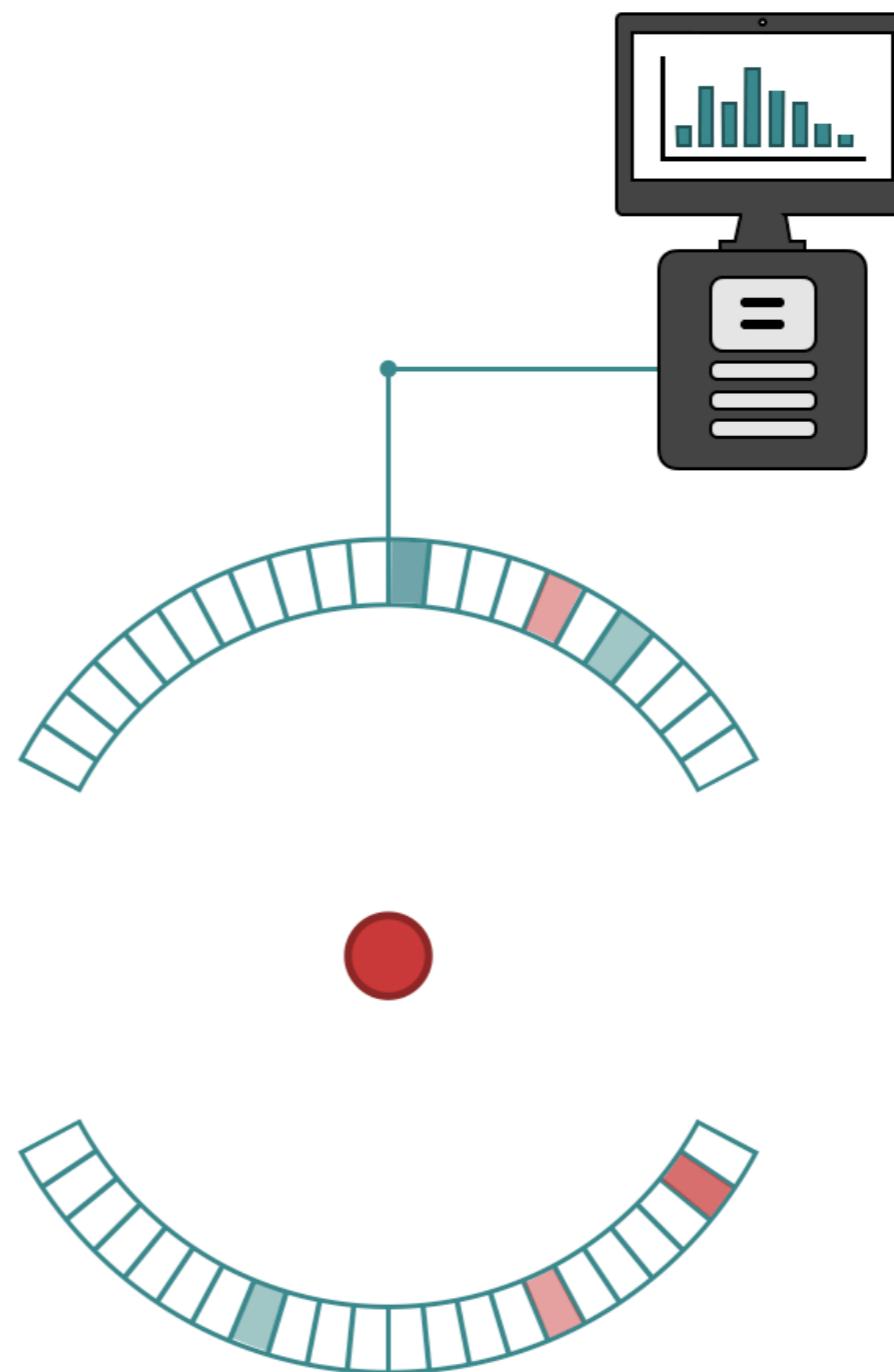

Resonance

Unstable hadron which decays via strong nuclear interaction

Has a mass *and* finite lifetime

$$\tau \sim 10^{-23} \text{ sec}$$

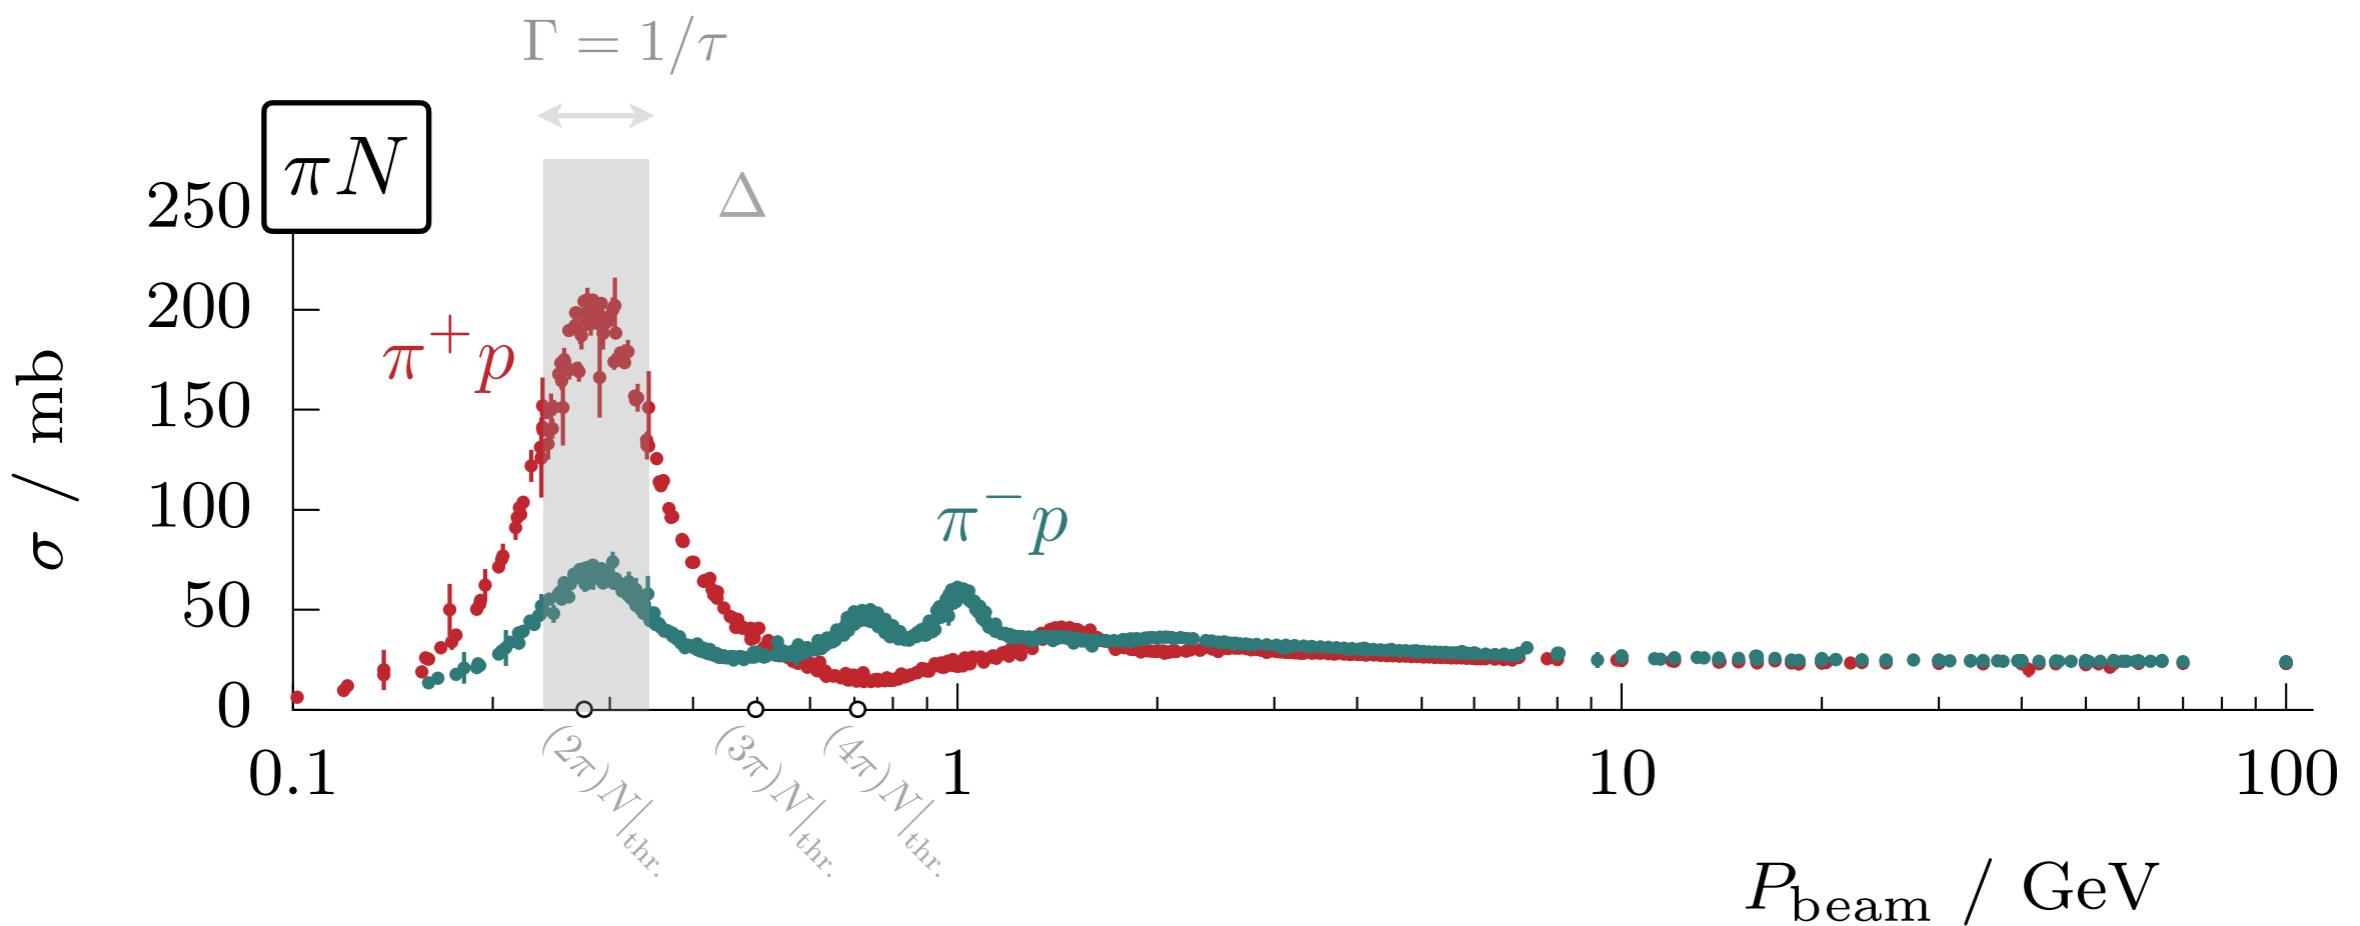

Most hadrons are resonances

Observing Hadrons

We observe strongly interacting hadrons through reactions in accelerators/colliders

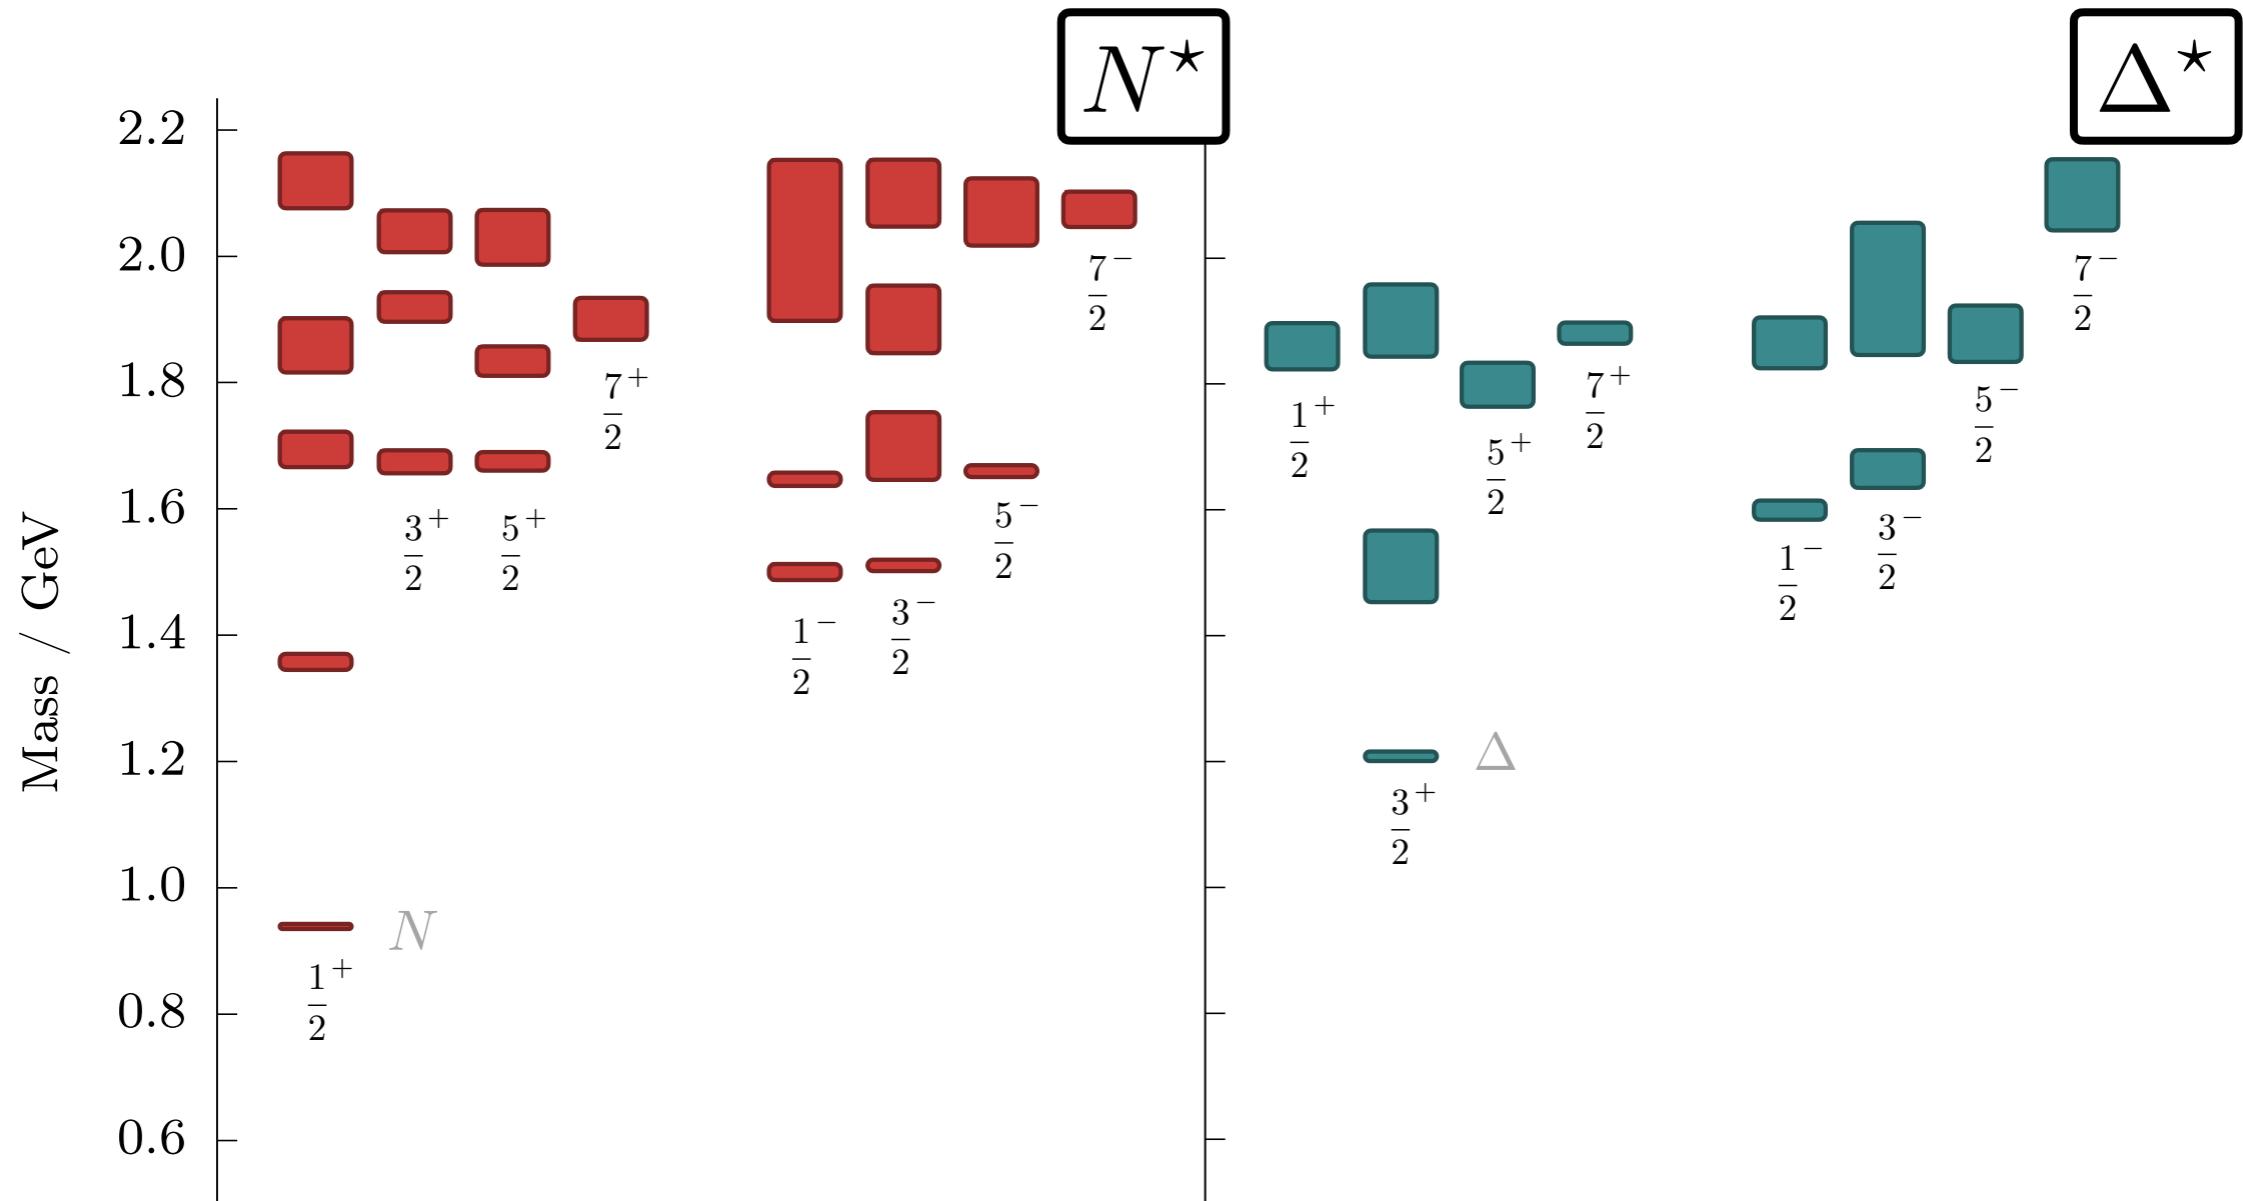

- If the interaction is sufficiently attractive, particles can form a **resonance**
- Resonances can appear as enhancements in the cross-section / amplitude

Observing Hadrons

We observe strongly interacting hadrons, through reactions in accelerators/colliders

- If the interaction is sufficiently attractive, particles can form a **resonance**
- Resonances can appear as enhancements in the cross-section / amplitude

Modern Nuclear Physics

Connect low-energy hadron & nuclear physics to **QCD**

- Quantitatively describe few-body reactions and their impact on observables
